Introduction

Traveling is an integral part of daily life, with air travel serving as a pivotal mode of transportation for over 30 million people each day. The impact of weather on air transport is a crucial factor that directly influences travel patterns and demand. In this project, we analyze Munich city weather data and air traffic from Munich airport spanning from 2000 to 2023 to discern the correlation between passenger numbers and weather conditions.

Analysis

—

Data Sources and Transformations

Munich weather data

We extracted and translated weather data from German to English, removing null values and sorting important metrics like air temperature, humidity, precipitation, and sunshine. The dataset was restructured to accurately capture monthly variations.

Munich airport air traffic data

Similar processes were followed for airport data, including extraction, translation, removal of irrelevant columns, and the addition of a passenger count column. Both datasets were then merged on common columns for further analysis.

Data Pipeline and Testing

Data pipeline creation

An automated data pipeline was developed using a Python script, fetching and processing datasets to generate SQLite databases. The pipeline ensures consistent data processing and maintenance, enhancing efficiency.

Testing and validation

The pipeline's reliability was verified through automated tests, including system-level scenarios ensuring the successful execution and output generation. Best practices like version control and data separation were also adhered to.

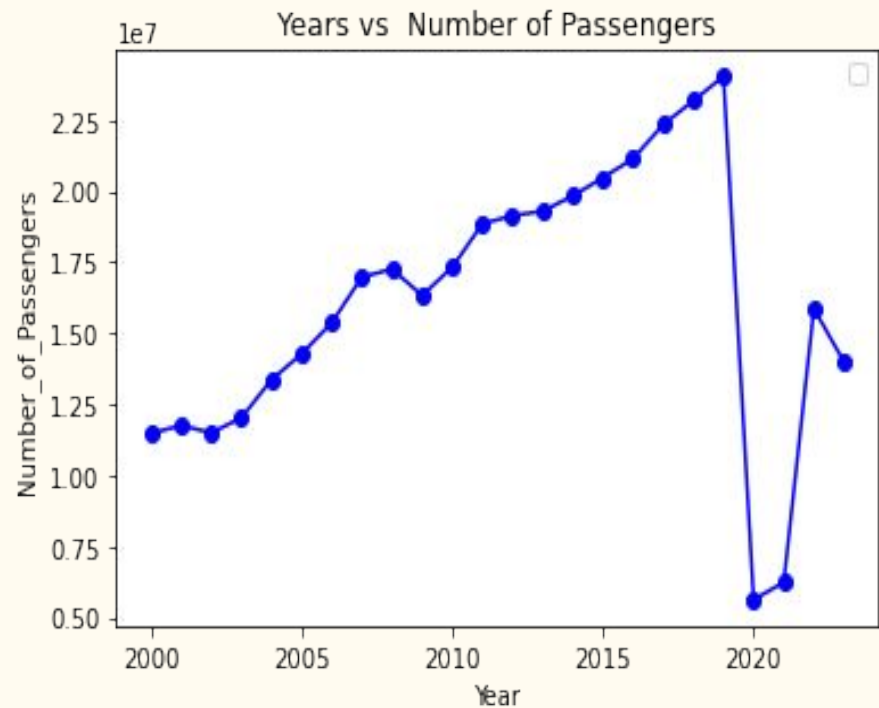

Analysis of Findings

Passenger trends over the years

The analysis revealed a consistent rise in passenger numbers, with a significant decline in 2020 due to the COVID-19 pandemic. However, thereafter, a resilient recovery was evident, especially in 2022 and 2023.

Monthly variation in passenger numbers

The data showcased a peak in travel during September, indicating a steady increase in passenger volume leading up to that month. Conversely, a decline was observed from September to December, reflecting seasonal travel patterns.

Impact of Weather on Passenger Travel

Weather influence on passenger arrivals

The study demonstrated that higher sunlight, humidity, and air temperature were positively associated with increased passenger arrivals at the airport, while increased precipitation had a negative correlation with passenger numbers.

Years vs Sunshine

Years vs Air_temperature

Conclusion

The comprehensive analysis revealed a strong interplay between weather conditions and passenger travel, with significant impacts observed during the COVID-19 pandemic. The insights gained from weather dynamics and their correlation with travel demand provide valuable guidance for operational and strategic decision-making in the air transportation industry.
